March 2021

1 Derivation

We start with the heat equation from equation 1.3 in "Drew's First Writeup". That equation states

$$M\dot{u} + Au = Bz \tag{1}$$

To make the notation more compatible with our current paper, we rewrite the equation with different letters and invert the mass matrix. Now, the differential equation is,

$$\dot{x}(t) = -M^{-1}Ax(t) + M^{-1}Bu(t) y(t) = Cx(t)$$
 (2)

Based on the above equation, the Lyapunov equation we want to solve is

$$(-M^{-1}A)P + P(-M^{-1}A)^{T} + CC^{T} = 0$$
(3)

The P in the above equation is the observability gramian.

Now, based on the "low rank smith" paper, we can rewirte the above equation as

$$P = (-M^{-1}A - \mu I)(-M^{-1}A + \mu I)^{-1}P(-M^{-1}A + \mu I)^{-1T}(-M^{-1}A - \mu I)^{T}$$
$$-2\mu(-M^{-1}A + \mu I)^{-1}CC^{T}((-M^{-1}A)^{T} + \mu I)^{-1}$$
(4)

Let's denote $A_{\mu}=(-M^{-1}A-\mu I)(-M^{-1}A+\mu I)^{-1}$. Then, we can simplify the above equation as

$$P = A_{\mu}PA_{\mu}^{T} - 2\mu(-M^{-1}A + \mu I)^{-1}CC^{T}((-M^{-1}A)^{T} + \mu I)^{-1}$$
(5)

Now, suppose we are inside the greedy algorithm and want to update the observability gramian with just one more sensor. We can write $P_{next} = P_{pre} + D$.

$$P_{pre} + D = A_{\mu}(P_{pre} + D)A_{\mu}^{T} - 2\mu(-M^{-1}A + \mu I)^{-1}(C_{pre} + C_{rank1})(C_{pre} + C_{rank1})^{T}((-M^{-1}A)^{T} + \mu I)^{-1}$$
(6)

When we do $(C_{pre} + C_{rank1})(C_{pre} + C_{rank1})^T$, the cross terms will cancel out. Furthermore, we know P_{pre} satisfies the Stein equation, which is equation 3.4 in the "low rank smith" paper. Therefore, we have

$$D = A_{\mu}DA_{\mu}^{T} - 2\mu(-M^{-1}A + \mu I)^{-1}C_{rank1}C_{rank1}^{T}((-M^{-1}A)^{T} + \mu I)^{-1}$$
(7)

Now, we use the infinite series expansion given in the stanford lecture,

$$D = \sum_{t=0}^{\infty} A_{\mu}^{t} (-2\mu(-M^{-1}A + \mu I)^{-1} C_{rank1} C_{rank1}^{T} ((-M^{-1}A)^{T} + \mu I)^{-1}) (A_{\mu}^{T})^{t}$$
(8)

or,

$$D = -2\mu \sum_{t=0}^{\infty} A_{\mu}^{t} (-M^{-1}A + \mu I)^{-1} C_{rank1} C_{rank1}^{T} ((-M^{-1}A)^{T} + \mu I)^{-1} (A_{\mu}^{T})^{t}$$
(9)

Now, we can write the D as

$$D = -2\mu(aa^T + bb^T + \dots) = -2\mu A_{sulvester} B_{sulvester}$$
(10)

Now, we have

$$det(P - 2\mu A_{sylester} B_{sylvester}) = det(P(I - 2\mu P^{-1} A_{sylvester} B_{sylvester}))$$

$$= det(P) det(I - 2\mu P^{-1} A_{sylvester} B_{sylvester})$$

$$= det(P) det(I - 2\mu B_{sylvester} P^{-1} A_{sylvester})$$
(11)

Now, a problem with the current formulation is that P is a low rank matrix and P^{-1} is numerically low rank. Therefore, instead of using $logdet(P_{next})$ as the objective function, we propose the following. In each iteration of the greedy algorithm, we already know P_{pre} and can use its top eigenvectors form a subspace. We know that P_{pre} in this subspace spanned by its own top eigenvectors can be inverted stably. Therefore, the new objective is $U'_{pre}P_{next}U_{pre}$, where U_{pre} is obtained by performing a diagonalization of $P_{pre} = U_{pre}\Sigma_{pre}U'_{pre}$. Therefore,

$$Objective = det(U'_{pre,top}P_{next}U_{pre,top})$$

$$= det(U'_{pre,top}(P_{pre} + D)U_{pre,top})$$

$$= det(\Sigma_{pre,top} + U'_{pre,top}DU_{pre,top})$$

$$= det(\Sigma_{pre,top} - 2\mu U'_{pre,top}A_{sylester}B_{sylvester}U_{pre,top})$$

$$= det(\Sigma_{pre,top})det(I - 2\mu B_{sylvester}U_{pre,top}\Sigma_{pre,top}^{-1}U'_{pre,top}A_{sylvester})$$

$$(12)$$

A new objective function.

$$Objective = det(P)det(I - 2\mu B_{sylvester}(P + \lambda I)^{-1} A_{sylvester})$$

$$= det(I - 2\mu B_{sylvester}(P + \lambda I)^{-1} A_{sylvester})$$
(13)

2 Implementation Detail

We notice that A_{μ} , $(-M^{-1}A + \mu I)^{-1}$, and $(-M^{-1}A)^T + \mu I)^{-1}$ are the same throughout the entire process. Therefore, we can compute those three matrices in advance. Furthermore, we can diagonalize $A_{\mu} = A_{\mu\nu}A_{\mu d}A_{\mu\nu}^{-1}$

Now, we can write the D as

$$D = -2\mu(aa^T + bb^T + \dots) \tag{14}$$

Furthermore, we have

$$D = -2\mu A_{sylvester} B_{sylvester} \tag{15}$$

$$A_{sylvester} = \begin{bmatrix} & | & | & \\ a & b & \dots \\ & | & | & \end{bmatrix}$$

$$B_{sylvester} = \begin{bmatrix} & - & a^T & - \\ - & b^T & - \\ & \vdots & & \end{bmatrix}$$

```
Algorithm 1: Optimal Sensor Placement With Approximate Observability Gramian
```

```
1.Initialize the algorithm with a very small set of sensors, selected\_obs.

2.Set \mu and max iteration for the Low Rank Smith method.

3.Set max terms for the infinite series and projection rank cutoff.

4.Compute A_{\mu}, which is A_{\mu} = (-M^{-1}A - \mu I)(-M^{-1}A + \mu I)^{-1}.

5.Diagonalize A_{\mu} so that A_{\mu} = V_{A_{\mu}}D_{A_{\mu}}V_{A_{\mu}}^{-1}.

6.Compute L = (-M^{-1}A + \mu I)^{-1} and R = ((-M^{-1}A)^T + \mu I)^{-1}.

for i = 0, 1, 2, ... max sensor do

1. Use the Low Rank Smith method to diagonalize the current observability gramian, Q, such that Q = U_{pre}\Sigma_{pre}U_{pre}

for j not in selected_obs do

1. Initialize A_{sylvester,j} = L(:,j) and denote L(:,j) = l_j

for k = 1, ... max terms do

1. A_{sylvester,column\_k} = V_{A_{\mu}}D_{A_{\mu}}^kV_{A_{\mu}}^{-1}l_j.

2. Append A_{sylvester,column\_k} as a new column to A_{sylvester,j}.

end

2. Set B_{sylvester,j} = A'_{sylvester,j}

3. Compute the objective function,
```

2. Select the ith sensor location based on the maximum value of the objective function

 $det(I - 2\mu B_{sylvester,j} U_{pre,top} \Sigma_{pre,top}^{-1} U'_{pre,top} A_{sylvester,j})$

3. Add this selected sensor to selected_obs end

end

Now, let's see the time complexity of the algorithm for adding one more sensor. The time complexity of diagonalizing the observability gramian at the first step of the i loop is bounded by $O(n^3)$

The time complexity of computing a term in the infinity series is $O(n^2)$ because l_j and r_j are rank 1 vectors. The rank of $I-2\mu B_{sylvester,j}U_{pre,top}\Sigma_{pre,top}^{-1}U'_{pre,top}A_{sylvester,j}$ is determined by the maximum number of terms in the infinity series expansion, and the time complexity of forming this matrix is $O(max_terms\ n\ projection_rank)$.

Therefore, the overall time complexity for computing one objective function is bounded by $O(kn^2)$, and k is the maximum number of terms we choose in the infinity series. Therefore, the overall time complexity of adding a new sensor is $O(kn^3)$. If we choose k to be 1, which seems to work. Then the time complexity of finding a new sensor is $O(n^3)$. The most naive method is $O(n^4)$.

3 Factor out the M matrix?

$$P = (-M^{-1}A - \mu I)(-M^{-1}A + \mu I)^{-1}P(-M^{-1}A + \mu I)^{-1T}(-M^{-1}A - \mu I)^{T}$$
$$-2\mu(-M^{-1}A + \mu I)^{-1}CC^{T}((-M^{-1}A)^{T} + \mu I)^{-1}$$
(16)

$$(-M^{-1}A - \mu I)(-M^{-1}A + \mu I)^{-1}$$

$$= (-M)^{-1}(A + \mu MI)\{(-M)^{-1}(A - \mu MI)\}^{-1}$$

$$= (-M)^{-1}(A + \mu MI)(A - \mu MI)^{-1}(-M)$$
(17)

$$P = (-M)^{-1}(A + \mu MI)(A - \mu MI)^{-1}(-M)P(-M)(A - \mu MI)^{-1T}(A + \mu MI)^{T}(-M)$$
$$-2\mu(-M^{-1}A + \mu I)^{-1}CC^{T}((-M^{-1}A)^{T} + \mu I)^{-1}$$
(18)

$$P = (-M)^{-1}(A + \mu MI)(A - \mu MI)^{-1}(-M)P(-M)(A - \mu MI)^{-1T}(A + \mu MI)^{T}(-M)$$
$$-2\mu(A - \mu MI)^{-1}(-M)CC^{T}((-M^{-1}A)^{T} + \mu I)^{-1}$$
(19)

$$((-M^{-1}A)^{T} + \mu I)^{-1}$$

$$= ((A(-M^{-1}) + \mu I)^{-1})$$

$$= \{(A - \mu IM)(-M)^{-1}\}^{-1}$$

$$= -M(A - \mu IM)^{-1}$$
(20)

$$P = (-M)^{-1}(A + \mu MI)(A - \mu MI)^{-1}(-M)P(-M)(A - \mu MI)^{-1T}(A + \mu MI)^{T}(-M)$$
$$-2\mu(A - \mu MI)^{-1}(-M)CC^{T}(-M)(A - \mu IM)^{-1}$$
(21)
